Understanding Maternal Morbidity and Mortality (MMM) in the Context of the Health of Women

MATERNAL HEALTH covers the health of women during the preconception, pregnancy, and postpartum periods. A series of important events and changes—physical, emotional, and social—occurs before, during, and well after the 40 weeks of gestation and the first year after childbirth. These changes are natural and may be new, unexpected, and joyful. But they may also be stressful and have health consequences across a woman’s life course.

The U.S. Department of Health and Human Services (HHS) defines women’s health as “diseases and conditions ... experienced by women across the lifespan and in the social context of their lives.” HHS sees pregnancy as an important part of the overall health of women. The National Institutes of Health (NIH), which is the Nation’s foremost medical research agency, encourages scientists to study pregnancy as part of the life course.

The World Health Organization (WHO) defines *maternal morbidity* as “any health condition attributed to and/or aggravated by pregnancy and childbirth that has a negative impact on the woman’s wellbeing.”¹

The Centers for Disease Control and Prevention (CDC) states: “*Severe maternal morbidity (SMM)* includes unexpected outcomes of labor and delivery that result in significant short- or long-term consequences to a woman’s health.”²

Severe Maternal Morbidity (SMM): What Are the Trends?

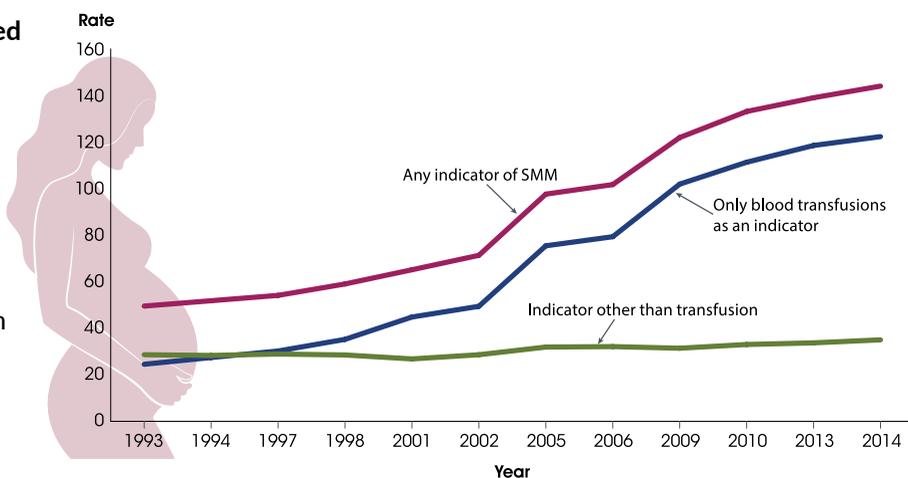

SMM affected more than **50,000 women** in the United States in 2014.² Rates of SMM have nearly doubled during the past decade.²

The need for blood transfusions is the most common indicator of SMM.²

For every pregnancy-related death in the United States, 70 women experience a “near miss” (SMM).²

SMM in the United States, 1993–2014

Rate of severe maternal morbidity per 10,000 delivery hospitalizations

Source: CDC, 2017²

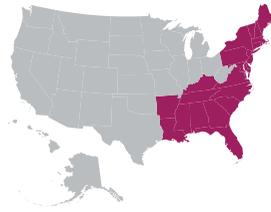

Who Is Most Affected by SMM?

More likely to occur for women who are:

- Age 20 or younger
- Age 40 or older
- Receiving Medicaid
- Residents of a low-income ZIP Code.

Source: Fingar et al., 2018³

More likely to occur at hospitals located in:

Source: Fingar et al., 2018³

From 2012 to 2015, compared with White women, the incidence of SMM was:

- 166% higher for Black women
- 122% higher for Hispanic women
- 117% higher for Asian/Pacific Islander women
- 148% higher for American Indian/Alaska Native women

Source: Admon et al., 2018⁴

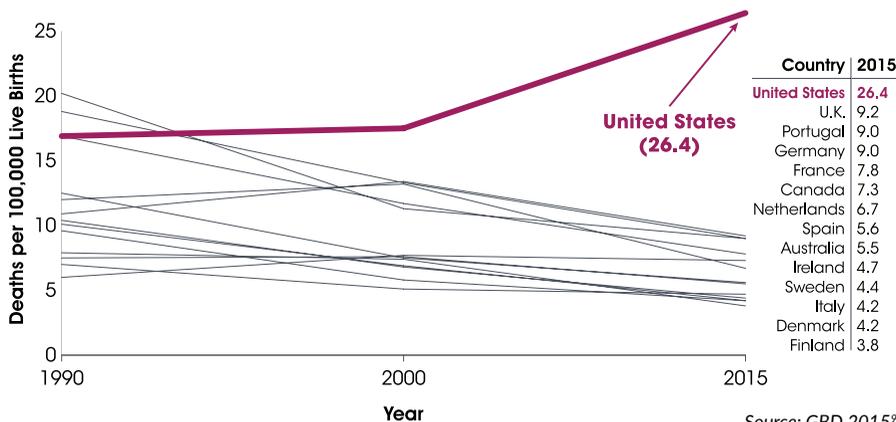

According to WHO: “Maternal death is the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental causes.”⁵

CDC uses the term “pregnancy-related death” and defines it as “the death of a woman while pregnant or within 1 year of the end of a pregnancy—regardless of the outcome, duration, or site of the pregnancy—from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes.”⁶

Maternal Mortality: What Are the Trends?

In 2018, **658 women** in the United States died while pregnant or within 42 days of the end of their pregnancy, for an overall maternal mortality rate of 17.4 deaths per 100,000 live births.⁷ Experts estimate that approximately **60%** of maternal deaths are preventable.⁸

The United States Has Highest Maternal Mortality Rate Among High-Income Countries⁹

Source: GBD 2015⁹
Credit: Rob Weychert/ProPublica.

While the U.S. maternal mortality rate increased by 16.7%, global maternal mortality rates decreased during the same period (1990–2015).¹⁰

Maternal Mortality: Who Is Most Affected?

Maternal Deaths (within 42 days of pregnancy), 2018 (deaths per 100,000 live births)

White 14.7

Black 37.1

Hispanic 11.8

Source: Hoyert & Miniño, 2020⁷

From 2011 to 2015, rates of maternal deaths were threefold higher for Blacks and twofold higher for American Indian/Alaska Natives than for Whites.⁸

Factors such as education and higher socioeconomic status do not mitigate the elevated risks of SMM and maternal mortality among Black women.¹¹

Among women living in the United States, **16.1%** of pregnancy-related deaths from 2011 to 2013 occurred in women born in another country.¹²

In 2018, the maternal mortality rate for women 40 years of age or older was **more than 7 times** the rate for women younger than 25.⁷

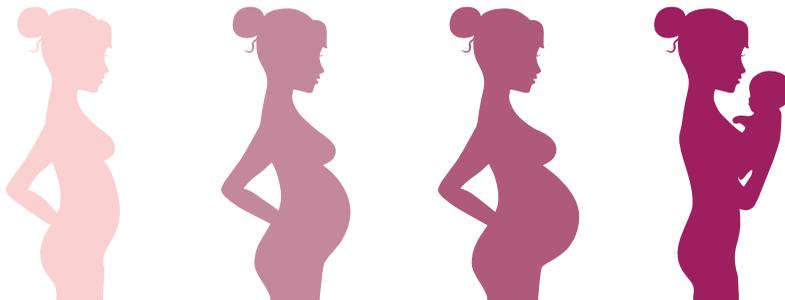

Maternal Mortality: When Does It Occur?

Understanding *when* pregnancy-related deaths occur—and the leading causes of those deaths during different periods—can help us prevent them. **More than half of pregnancy-related deaths occur after delivery.**

In 2018, there were 277 late maternal deaths, for a rate of 7.3 (deaths per 100,000 live births).⁷ Late maternal deaths are not included as part of the official maternal mortality rate.⁷ A significant proportion of pregnancy-related deaths occur

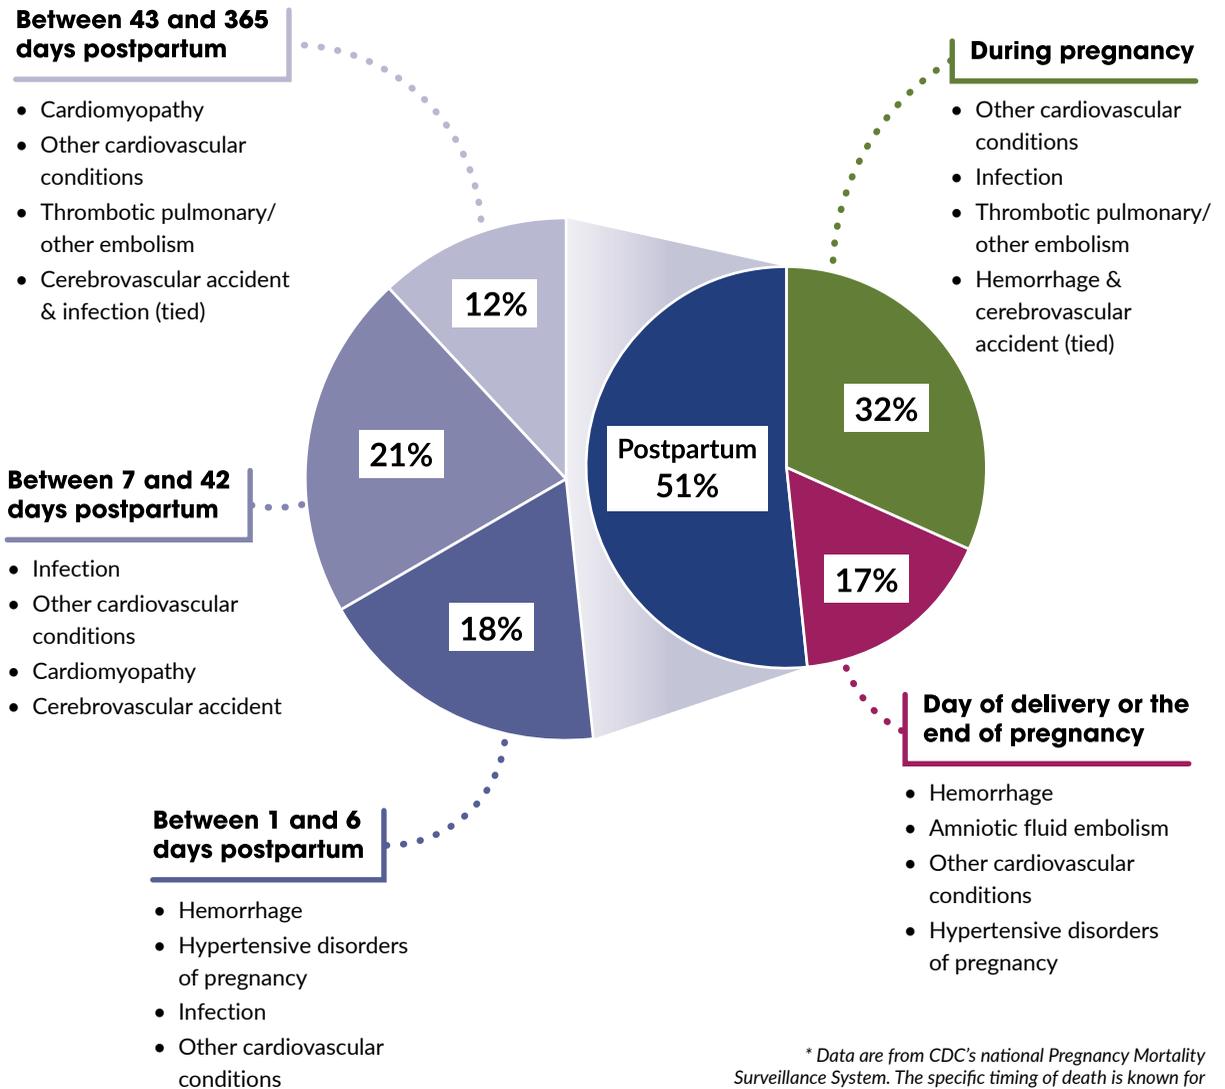

between 43 and 365 days after delivery (late maternal deaths).¹³ The leading causes of pregnancy-related deaths varied by the timing of death.¹³

The postpartum period has been called the “fourth trimester”—in which it is recommended that each woman have contact with obstetric providers within the first 3 weeks after delivery and receive ongoing care tailored to her individual needs.¹⁴

Pregnancy-Related Deaths by Timing of Death Relative to Pregnancy, 2011–2016*

(Four leading causes of death shown for each time period)

* Data are from CDC's national Pregnancy Mortality Surveillance System. The specific timing of death is known for almost 88% of the pregnancy-related deaths from this time. Source: Government Accountability Office, 2020.¹³

What Factors Influence MMM?

Preconception Health

Preconception health is the health of women prior to becoming pregnant during their reproductive years.¹⁵

Risk Factors Include...

diabetes, hypertension, and current cigarette smoking

Health-Promoting Factors Include...

normal weight, recommended physical activity, and a healthy diet with a variety of fruits, vegetables, whole grains, and folic acid supplements (at least 400 micrograms daily).¹⁶

Generally, risk factors are highest and health-promoting factors lowest for **women ages 35–44, Black women, women without insurance, and those residing in Southern States.**¹⁵

From 2008 to 2012, **43%** of women delivering in a hospital had risk factors for SMM—a **preexisting chronic disease, a pregnancy-associated disease, or advanced maternal age.** This represents a **23.5%** increase since 1993–1997.¹⁷

Behavioral Risk Factors

Smoking

Smoking during pregnancy increases the risk of complications, such as placenta previa, placental abruption, and premature rupture of the membranes.¹⁸

Among pregnant women between 2010 and 2013:

- **About 16%** used tobacco during the previous month
- **About 11%** had tobacco dependence during the previous month¹⁹

Overweight and Obesity

Among pregnancy-related deaths from 2011 to 2013, **16.9%** occurred among women who were obese before pregnancy.¹²

In 2014, **about half** of women were **overweight or obese** before they became pregnant.²⁰

Opioid Use, Overdose, and Suicide

Between 2004–2005 and 2014–2015, opioid-related deliveries increased from 1.5 to 6.5 per 1,000 delivery hospitalizations.²¹

2016 (10%)

250%

2007 (4%)

The percentage of pregnancy-associated deaths involving opioids more than doubled between 2007 and 2016.²²

The increase in pregnancy-associated deaths involving opioids was more prominent among **White women.**²²

In 2016, **78%** of pregnancy-associated deaths involving opioids were caused by heroin or synthetic opioids (e.g., fentanyl)—an increase of **17%** since 2007.²²

Experts estimate that up to **15%** of U.S. women who are pregnant or postpartum (up to 1 year after delivery) die from self-harm, including overdose and suicide.²³

Prenatal Care

Poor prenatal care utilization—late onset of care, fewer visits, or both—significantly increases the risks of insufficient gestational weight gain, prenatal smoking, premature rupture of membranes, precipitous labor, no breastfeeding, maternal postnatal underweight, and postpartum smoking.²⁴

In 2016, **15% of women received inadequate prenatal care.**

Younger women, women with less education, women having a fourth or higher-order birth, and non-Hispanic Native Hawaiian and other Pacific Islander women were least likely to begin care in the first trimester of pregnancy and have at least adequate prenatal care.²⁵

Among women who had pregnancy-related deaths and whose prenatal care status was known, **8.5%** had not received any prenatal care and **24.5%** started prenatal care in their second or third trimester.¹²

Severe Maternal Morbidity: Short-Term Risks

SMM is stressful and affects the woman, her family and friends, and the overall community. For example, women who experience SMM may be at increased risk of post-traumatic stress disorder symptoms during the 6–8 weeks after delivery.²⁶

Single-State studies suggest that

1. Subsequent hospitalizations during the year after delivery may be higher for women who experience SMM, even when those with preexisting chronic conditions are excluded²⁷
2. Women with SMM may have an increased likelihood for emergency department visits 90 days after delivery²⁸
3. Women with hypertensive disorders of pregnancy (HDP) have higher hospitalization readmission rates for cardiovascular disease, with Black women having a higher rate than White and Hispanic women²⁹

The average hospital cost of a delivery without SMM was **\$4,300**, compared with **\$11,000** for a delivery with any SMM, from 2011 to 2012.³⁰

How Does Maternal Health Affect Women Across the Life Course?

Condition During Pregnancy	Risk for Disease in Later Life
<p>Gestational diabetes mellitus (GDM): Prevalence is estimated at 7.6% in the United States.³¹</p>	<p>Increased risk of type 2 diabetes mellitus (T2DM): Among women with GDM, 52.2% developed a glucose metabolism disorder 10 to 14 years postpartum, compared with 20.1% of those without GDM—a more than threefold increased risk.³²</p>
<p>Preeclampsia: About 5% of hospital deliveries involved preeclampsia/eclampsia in 2014.³³</p> 	<p>Increased risk of hypertension (HTN), cardiovascular disease (CVD), and cardiovascular accident (CVA): Women with early-onset (<34 weeks) hypertensive disorders of pregnancy have more than twice the risk of developing incident CVD and more than a fourfold risk of developing incident HTN.³⁴</p> <p>Preeclampsia increases the risk of incident heart failure in later life fourfold.³⁵</p> <p>Preeclampsia doubles the risk of coronary heart disease, stroke, and death because of coronary heart disease or CVD.³⁵</p>
<p>Complicated vaginal delivery: The vast majority of hospital stays for vaginal delivery (91.3%) involved at least one complicating condition in 2009.³⁶</p> <p>Forceps vaginal delivery numbered 16.2 per 1,000 stays.³⁶</p> <p>Perineal laceration (any degree of tear of the tissues that separate the vagina from the anus) numbered 585.7 per 1,000 stays.³⁶</p>	<p>Increased risk of pelvic floor disorders: Five to ten years after a first delivery:</p> <ul style="list-style-type: none"> • Forceps delivery increased the odds of pelvic floor disorders—with almost a threefold risk for overactive bladder and nearly double the risk for pelvic organ prolapse (POP).³⁷ • A history of spontaneous perineal laceration more than doubled the risk for POP.³⁷ • Operative vaginal delivery increased the risk for POP more than sevenfold.³⁸ • Operative vaginal delivery was associated with almost double the risk of anal incontinence and POP compared with spontaneous vaginal delivery.³⁹
<p>Depression/Anxiety: In one study, 6.4% of women in the first trimester, 3.9% of women in the third trimester, and 6.9% of postpartum women (3–5 months) had experienced serious psychological distress (SPD)* during the previous month.⁴⁰</p> <p>The overall prevalence of postpartum depressive symptoms was 11.5% for women in 27 States in 2012.⁴¹</p> <p>Among females ages 14–49 who were hospitalized for delivery from 2004 to 2013, 2.8% had a diagnosis of depression and/or anxiety.⁴²</p>	<p>Increased risk of depression and anxiety: Servicewomen who were first-time mothers and experienced postpartum depression from 1998 to 2010 were more than seven times more likely to experience depressive disorders, more than three times more likely to experience anxiety disorders, and more than four times more likely to experience bipolar disorders subsequently compared with women without postpartum depression.⁴³</p> <p>Women whose postpartum depression persisted for 8 months showed elevated depressive symptoms up to 11 years after childbirth, according to a study of U.K. mothers.⁴⁴</p>

*SPD was assessed with questions about how nervous, hopeless, restless or fidgety, sad or depressed, or worthless the respondent felt and to what extent everything felt like an effort.

What Are the Opportunities for Intervention or Prevention?

Prevention and Intervention Strategies	Impact on Risk for Disease in Later Life
Pioglitazone ⁴⁵ 	Leads to a diabetes rate of 4.6% per year during treatment for 3 years, compared with a rate of 12.1% per year during placebo treatment ⁴⁵
Intensive lifestyle changes ⁴⁶	Reduced progression to T2DM by 35% compared with placebo ⁴⁶
Metformin ⁴⁶	Reduced progression to T2DM by 40% compared with placebo ⁴⁶
Screening for preeclampsia with blood pressure measurements throughout pregnancy, recommended by the U.S. Preventive Services Task Force ⁴⁷	
Regularly taking aspirin ⁴⁸	Eliminates increased risk (1.5 times increased likelihood) of CVA among women age 60 or younger with any prior hypertensive disorders of pregnancy ⁴⁸
Lifestyle interventions (exercise, diet, and smoking cessation) ⁴⁹ 	Decreases cardiovascular risk by about 10% among women with a preeclampsia history ⁴⁹
Cesarean delivery [†]	Associated with about a 50% lower risk of stress urinary incontinence and overactive bladder and a 70% lower risk of POP compared with spontaneous vaginal delivery ³⁹
[†] Cesarean delivery is an important risk factor for SMM but does not necessarily explain the increasing trend in SMM ⁵⁰	
Screening for perinatal depression, recommended by the American College of Obstetricians and Gynecologists ⁵¹ 	Lack of research on specific interventions to prevent depression among women who have experienced postpartum depression 

How Are HHS Agencies Addressing MMM?

Arena of Collaboration

NIH makes a substantial investment in research to enhance maternal health and identify the causes of MMM. In 2017, NIH expenditures on maternal health research totaled more than \$330 million.

A wide range of NIH Institutes, Centers, and Offices (ICOs) support research activities on various aspects of maternal health within their areas of scientific expertise, including the following:

- Leveraging NIH collaborative research and clinical trials networks
- Investigating factors underlying SMM and ways to address disparities
- Addressing chronic conditions that influence MMM (e.g., hypertension)
- Conducting basic and preclinical research on the mechanisms underlying pregnancy-related conditions and risk for disease in later life
- Improving the application of health technology and management of pregnancy-related conditions

In 2017, NIH created an official reporting category for maternal health. Estimates of NIH funding for maternal health are available to the public via the [NIH Research Portfolio Online Reporting Tools](#). Although the majority (about 51%) of the research was funded by the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD), 19 other ICOs funded one or more research projects. NIH research on the health of women and maternal health considers the entire life course of women as an integrated whole rather than compartmentalizing distinct stages or events, and it encompasses everything that affects women—from head to toe, including both body and mind. NIH recognizes that the health of women is affected by the complex intersection of multiple factors at the levels of the individual, family, community, and society. Biological factors intersect with the social and contextual aspects of a woman’s life to affect overall health, as well as pregnancy and peripartum periods. To improve the understanding of pregnancy, NICHD initiated a research project called [PregSource®](#): Crowdsourcing to Understand Pregnancy. This project gathers firsthand

FY 2019 NIH Investments in Maternal Health

Dollar Investment (millions)

NOTE: See page 15 for the list of funding ICOs

* NIAAA, NIBIB, NIDCR, and NIAMS

information about pregnancy from pregnant women through confidential online questionnaires. More information on NIH's efforts to improve maternal health—and the health of all women—can be found in the [Trans-NIH Strategic Plan for Women's Health Research](#).

What's Next? An NIH Approach to MMM

Representatives from ICOs that support research on maternal health have joined together to develop a plan aimed at identifying needed studies and additional efforts that will address many of the antecedents and consequences of MMM. Such research would aim to do the following:

- Enhance health disparities research to reduce adverse pregnancy-related outcomes
- Increase understanding of social determinants and risk factors for MMM
- Improve antepartum, intrapartum, and postpartum care and the management of complications
- Define environmental risk factors, such as the microbiome, exogenous hormones, and environmental toxins
- Provide insight into psychosocial exposures, including stress, discrimination, and caregiving
- Understand coping behaviors in women with SMM and families experiencing a maternal mortality
- Investigate the potential effects of implicit bias on the health care system regarding pregnancy

Federal Partners Working to Reduce MMM

CDC supports States as they track SMM and pregnancy-related deaths, and these data are used to guide care for pregnant women. In the maternal health area, CDC focuses on epidemiology, surveillance, environmental approaches, health care system interventions, and community programs linked to clinical services. CDC also works with public health agencies, community organizations, and other partners to improve the health of women before, during, and after pregnancy. For more information on CDC's efforts, please visit the [CDC Maternal and Infant Health webpage](#).

The Health Resources and Services Administration (HRSA) is working to reduce SMM and maternal mortality through health promotion, risk reduction, and training the health care workforce to identify and treat early warning signs. HRSA efforts focus on implementing best practices—including through the Alliance for Innovation on Maternal Health and Safety (AIM) initiative, which works with States and hospitals to implement “maternal safety bundles”—partnering with local communities and sparking innovative solutions. The HRSA Health Center Program provides affordable and accessible primary, prenatal, and perinatal care (among other health services) to approximately 7 million women of reproductive age across the country. HRSA also helps train health care providers and supports data collection and research.⁵² For more information on HRSA efforts, please see the [HRSA's How We Improve Maternal Health webpage](#).

The Food and Drug Administration (FDA) promotes and protects maternal health through numerous programs, initiatives, and collaborations with internal and external stakeholders. The FDA Office of Women's Health (OWH) funds research pertinent to pregnancy and lactation and also maintains a public website that includes a listing of pregnancy exposure registries, serving as a resource for consumers and health care providers. OWH also provides other consumer-friendly resources to educate pregnant and postpartum women about medicines, foods, and other products. The Division of Pediatric and Maternal Health (DPMH) in the Center for Drug Evaluation and Research develops

clinically relevant, evidence-based prescription product and over-the-counter product labeling and other communications that facilitate informed use of drugs and biologics for pregnant and nursing women. DPMH also develops guidance to help drug developers and researchers, including recently published draft guidance titled “Pregnant Women: Scientific and Ethical Considerations for Inclusion in Clinical Trials.” This guidance provides recommendations on how and when to include pregnant women in clinical trials during drug development. In addition, the National Center for Toxicological Research spearheaded the formation of the virtual Perinatal Health Center of Excellence, which is focused on the perinatal period, defined as including the maternal, premature, and neonatal periods and development throughout childhood. For more information on FDA’s efforts, please visit [DPMH’s website](#).

As of April 2020, HHS had 13 ongoing funding efforts aimed at reducing pregnancy-related deaths.¹³ These are described below.

Ongoing HHS Efforts Focused on Reducing Pregnancy-Related Deaths

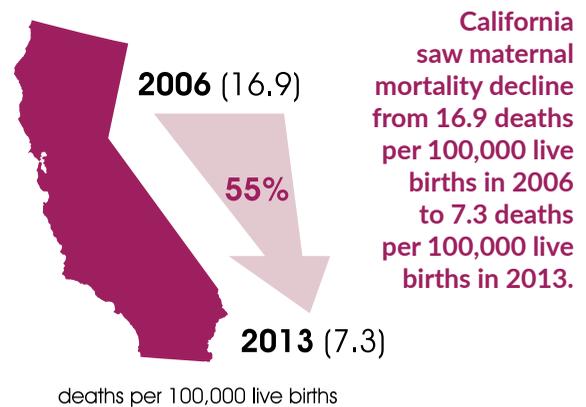

Funding Opportunity	Purpose
Preventing Maternal Deaths: Supporting Maternal Mortality Review Committees (MMRCs)	Funds State agencies and organizations that coordinate and manage MMRCs to collect the most detailed, complete data on pregnancy-related deaths. In 2019, HHS awarded 24 recipients (covering 25 States) 5-year cooperative agreements
Title V Maternal and Child Health (MCH) Services Block Grant Program	Provides funding to 59 States and jurisdictions to improve MCH and supports promotion of health and well-being before, during, and after pregnancy
State-based Perinatal Quality Collaboratives (PQCs)	Supports States’ ability to enhance the capacity of PQCs
National Network of Perinatal Quality Collaboratives	Supports PQCs nationwide to improve care and programming related to maternal and infant health
Stop The Clot, Spread The Word	Supports national digital campaigns that provide information on the risk factors, signs, and symptoms of blood clots
Alliance for Innovation on Maternal Health (AIM)	Supports efforts to reduce maternal deaths and SMM by engaging provider organizations
AIM Community Care Initiative	Supports the development and implementation of nonhospital-focused maternal safety bundles within community-based organizations and outpatient clinical settings
Healthy Start Grant Awards	Support the hiring of clinical providers who will give direct access to well-woman and maternity care
Rural Maternity and Obstetrics Management Strategies Program	Supports efforts to improve access to and continuity of maternal and obstetrics care in rural communities
State Maternal Health Innovation Support and Implementation Program	Strengthens partnerships and collaboration by establishing a State-focused maternal health task force
Supporting Maternal Health Innovation Program	Supports HRSA award recipients who focus on improving maternal health, States, and key stakeholders in their efforts to reduce and prevent maternal mortality and SMM
HRSA-supported research	The Maternal and Child Health Bureau supports the Maternal and Child Health Extramural Research Program
NIH-supported research	NIH funds maternal health through a number of its ICOs

Source: Government Accountability Office, 2020.¹³

Conclusion

There are many efforts to address MMM across the country. For example, States are working to improve the quality and safety of perinatal care as part of [CDC's National Network of Perinatal Quality Collaboratives](#). Through the HRSA-supported AIM initiative, the [Council on Patient Safety in Women's Health Care](#) has developed "bundles"—toolkits with evidence-driven practices for maternity care—that are endorsed by many multidisciplinary health professional societies.⁵³ Importantly, there is an AIM patient safety bundle to address racial and ethnic disparities in maternal health. Hospitals can download these patient safety bundles and obtain resources on implementing them. To see what maternal health looks like when such initiatives are implemented, one can look at California. In 2006, California established a public-private partnership to improve maternal health, and by 2013, the State had cut its maternal mortality rate by more than half—to a rate comparable to the average in western Europe.^{54,55} Please visit the [California Maternal Quality Care Collaborative website](#) for toolkits and other resources.

These efforts to improve the quality and safety of maternal care are very valuable. But it is also critical to improve the health of women across the life course—including preconception health and treating chronic conditions—and address the social determinants of health to reduce MMM. Passage of the Preventing Maternal Deaths Act of 2018 was a big step toward reducing maternal mortality.⁵⁶ This law authorizes Federal funding to bolster maternal mortality review committees (also called MMRCs) in all States, which should help standardize data collection across the country.⁵⁶ Awareness of MMM in the United States seems to be increasing, which is also important for mobilizing efforts to address this crucial issue.
